pd.set_option('display.max_columns', 500)
```

Here is the information on this particular data set:

0. loan\_amnt : The listed amount of the loan applied for by the borrower. If at some point in time, the credit department reduces the loan amount, then it will be reflected in this value.
1. term : The number of payments on the loan. Values are in months and can be either 36 or 60.
2. int\_rate : Interest Rate on the loan
3. installment : The monthly payment owed by the borrower if the loan originates.
4. grade LC : assigned loan grade
5. sub\_grade LC : assigned loan subgrade
6. emp\_title : The job title supplied by the Borrower when applying for the loan.
7. emp\_length : Employment length in years. Possible values are between 0 and 10 where 0 means less than one year and 10 means ten or more years.
8. home\_ownership : The home ownership status provided by the borrower during registration or obtained from the credit report. Our values are: RENT, OWN, MORTGAGE, OTHER
9. annual\_inc : The self-reported annual income provided by the borrower during registration.
10. verification\_status : Indicates if income was verified by LC, not verified, or if the income source was verified
11. issue\_d : The month which the loan was funded
12. loan\_status : Current status of the loan
13. purpose : A category provided by the borrower for the loan request.

14. title : The loan title provided by the borrower
15. zip\_code : The first 3 numbers of the zip code provided by the borrower in the loan application.
16. addr\_state : The state provided by the borrower in the loan application
17. dti : A ratio calculated using the borrower's total monthly debt payments on the total debt obligations, excluding mortgage and the requested LC loan, divided by the borrower's self-reported monthly income.
18. earliest\_cr\_line : The month the borrower's earliest reported credit line was opened
19. open\_acc : The number of open credit lines in the borrower's credit file.
20. pub\_rec : Number of derogatory public records
21. revol\_bal : Total credit revolving balance
22. revol\_util : Revolving line utilization rate, or the amount of credit the borrower is using relative to all available revolving credit.
23. total\_acc : The total number of credit lines currently in the borrower's credit file
24. initial\_list\_status : The initial listing status of the loan. Possible values are – W, F
25. application\_type : Indicates whether the loan is an individual application or a joint application with two co-borrowers
26. mort\_acc : Number of mortgage accounts.
27. pub\_rec\_bankruptcies : Number of public record bankruptcies

## Correlation Heatmap -

A correlation heatmap is a heatmap that shows a 2D correlation matrix between two discrete dimensions, using colored cells to represent data from usually a monochromatic scale. The values of the first dimension appear as the rows of the table while of the second dimension as a column. The color of the cell is proportional to the number of measurements that match the dimensional value. This makes correlation heatmaps ideal for data analysis since it makes patterns easily readable and highlights the differences and variation in the same data. A correlation heatmap, like a regular heatmap, is assisted by a colorbar making data easily readable and comprehensible.

In [ ]:

```
plt.figure(figsize=(12, 8))
sns.heatmap(data.corr(method='spearman'), annot=True, cmap='viridis')
plt.show()
```

We noticed almost perfect correlation between "loan\_amnt" the "installment" feature.

- installment: The monthly payment owed by the borrower if the loan originates.
- loan\_amnt: The listed amount of the loan applied for by the borrower. If at some point in time, the credit department reduces the loan amount, then it will be reflected in this value.

So, we can drop either one of those columns.

In [ ]:

```
data.drop(columns=['installment'], axis=1, inplace=True)
```

In [ ]:

```
plt.figure(figsize=(12, 8))
sns.heatmap(data.corr(method='spearman'), annot=True, cmap='viridis')
plt.show()
```

## Data Exploration -

1. The no of people those who have fully paid are 318357 and that of Charged Off are 77673.

In [ ]:

```
data.groupby(by='loan_status')[ 'loan_amnt' ].describe()
```

Out[19]:

	count	mean	std	min	25%	50%	75%	max
<b>loan_status</b>								
<b>Charged Off</b>	45368.0	15135.654536	8484.848789	1000.0	8700.0	14000.0	20000.0	40000.0
<b>Fully Paid</b>	186378.0	13857.548101	8302.548155	500.0	7500.0	12000.0	19200.0	40000.0

2. The majority of people have home ownership as Mortgage and Rent.

In [ ]:

```
data['home_ownership'].value_counts()
```

Out[20]:

```
MORTGAGE      116104
RENT           93551
OWN            22010
OTHER           59
NONE           19
ANY             3
Name: home_ownership, dtype: int64
```

3. Combining the minority classes as 'OTHER'.

In [ ]:

```
data.loc[(data.home_ownership == 'ANY') | (data.home_ownership == 'NONE'), 'home_ownership'].value_counts()
```

Out[21]:

```
MORTGAGE      116104

(106356, 48)

### MinMaxScaler -

For each value in a feature, MinMaxScaler subtracts the minimum value in the feature and then divides by the range. The range is the difference between the original maximum and original minimum.

MinMaxScaler preserves the shape of the original distribution. It doesn't meaningfully change the information embedded in the original data.

In [ ]:

```
scaler = MinMaxScaler()  
X_train = scaler.fit_transform(X_train)  
X_test = scaler.transform(X_test)
```

## Logistic Regression

In [ ]:

```
logreg = LogisticRegression(max_iter=1000)  
logreg.fit(X_train, y_train)
```

Out[51]:

LogisticRegression(max\_iter=1000)

In [ ]:

```
y_pred = logreg.predict(X_test)  
print('Accuracy of Logistic Regression Classifier on test set: {:.3f}'.format(logreg
```

Accuracy of Logistic Regression Classifier on test set: 0.890

### Confusion Matrix -

In [ ]:

```
confusion_matrix = confusion_matrix(y_test, y_pred)  
print(confusion_matrix)
```

[[85365 523]

[11131 9337]]

### Classification Report -

In [ ]:

```
print(classification_report(y_test, y_pred))
```

	precision	recall	f1-score	support
0	0.88	0.99	0.94	85888
1	0.95	0.46	0.62	20468
accuracy			0.89	106356
macro avg	0.92	0.73	0.78	106356
weighted avg	0.90	0.89	0.87	106356

## ROC Curve -

An ROC curve (receiver operating characteristic curve) is a graph showing the performance of a classification model at all classification thresholds. This curve plots two parameters:

- True Positive Rate
- False Positive Rate

True Positive Rate (TPR) is a synonym for recall and is therefore defined as follows:

- $TPR = TP / (TP + FN)$

False Positive Rate (FPR) is defined as follows:

- $FPR = FP / (FP + TN)$

An ROC curve plots TPR vs. FPR at different classification thresholds. Lowering the classification threshold classifies more items as positive, thus increasing both False Positives and True Positives. The following figure shows a typical ROC curve.

## AUC (Area under the ROC Curve) -

AUC stands for "Area under the ROC Curve." That is, AUC measures the entire two-dimensional area underneath the entire ROC curve (think integral calculus) from (0,0) to (1,1).

AUC provides an aggregate measure of performance across all possible classification thresholds. One way of interpreting AUC is as the probability that the model ranks a random positive example more highly than a random negative example. For example, given the following examples, which are arranged from left to right in ascending order of logistic regression predictions:

In [ ]:

```
logit_roc_auc = roc_auc_score(y_test, logreg.predict(X_test))
fpr, tpr, thresholds = roc_curve(y_test, logreg.predict_proba(X_test)[:,1])
plt.figure()
plt.plot(fpr, tpr, label='Logistic Regression (area = %0.2f)' % logit_roc_auc)
plt.plot([0, 1], [0, 1], 'r--')
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('Receiver operating characteristic')
plt.legend(loc="lower right")
plt.savefig('Log_ROC')
plt.show()
```

In [ ]:

```
def precision_recall_curve_plot(y_test, pred_proba_c1):
    precisions, recalls, thresholds = precision_recall_curve(y_test, pred_proba_c1)

    threshold_boundary = thresholds.shape[0]
    # plot precision
    plt.plot(thresholds, precisions[0:threshold_boundary], linestyle='--', label='pr
    # plot recall
    plt.plot(thresholds, recalls[0:threshold_boundary], label='recalls')

    start, end = plt.xlim()
    plt.xticks(np.round(np.arange(start, end, 0.1), 2))

    plt.xlabel('Threshold Value'); plt.ylabel('Precision and Recall Value')
    plt.legend(); plt.grid()
    plt.show()

precision_recall_curve_plot(y_test, logreg.predict_proba(X_test)[: ,1])
```

## Multicollinearity check using Variance Inflation Factor (VIF) -

Multicollinearity occurs when two or more independent variables are highly correlated with one another in a regression model. Multicollinearity can be a problem in a regression model because we would not be able to distinguish between the individual effects of the independent variables on the dependent variable.

Multicollinearity can be detected via various methods. One such method is Variance Inflation Factor aka VIF. In VIF method, we pick each independent feature and regress it against all of the other independent features. VIF score of an independent variable represents how well the variable is explained by other independent variables.

VIF =  $1/(1-R^2)$

In [ ]:

```
def calc_vif(X):
    # Calculating the VIF
    vif = pd.DataFrame()
    vif['Feature'] = X.columns
    vif['VIF'] = [variance_inflation_factor(X.values, i) for i in range(X.shape[1])]
    vif['VIF'] = round(vif['VIF'], 2)
    vif = vif.sort_values(by='VIF', ascending = False)
    return vif

calc_vif(X)[:5]
```

Out[57]:
